ABSTRACT

Torben Trier Christiansen 2019. Metal-detected Late Iron Age and Early Medieval Brooches from the Limfjord Region, Northern Jutland: Production, Use and Loss.

Journal of Archaeology and Ancient History. 2019, No. 24 pp 1–26. <http://urn.kb.se/resolve?urn=urn:nbn:se:uu:diva-378185>

Based on the study of 1,859 metal-detected brooches recovered at different sites in the Limfjord region, this paper discusses patterns of production, distribution, use, and deposition of brooches. Widespread indications of non-ferrous metalwork and a modest number of models for brooch production suggest that brooches were produced at many settlements in the region during the period studied (AD 400–1150), and traces of technical change and varying distribution patterns in the finished brooches suggest temporally as well as spatially differing modes of production. Furthermore, analyses suggests that most brooches were intact when they entered the soil, and seemingly random distribution patterns likely reflect the fact that many, perhaps most, were simply accidentally dropped. However, over and above, the interpretational difficulties are consequent on the recovery of all of the metal-detector finds in the plough layer detached from their original context. The interpretation of distribution patterns is at most sites also markedly challenged by the fact that many brooches, along with other metal artefacts, appear to having been secondarily deposited in the fields surrounding the settlements, probably during the manuring of the fields.

Metal-detected Late Iron Age and Early Medieval Brooches from the Limfjord Region, Northern Jutland: Production, Use and Loss

Introduction

Most Danish scholars perceive the past three decades of private metal detecting as a great success – and for good reason. Encouraged by liberal legislation and cooperative local museums, and favoured by the fact that more than 60 per cent of Denmark is arable land, private detectorists have saved thousands of objects from slow degradation in the hostile environment of the plough layer through their hobby. In addition to generally multiplying previously scarce find categories, thus radically altering many distribution maps, these finds have led to the recovery of a broad variety of settlements, changing the general perception of settlement and societal development during the Iron Age and the Early Medieval period in Denmark (e.g. Watt 1991; Jensen & Watt 1993; Jørgensen 1994; Randsborg 1994; Fabeck & Ringtved 1995; Fabeck 1999; Nielsen 2002; Høilund Nielsen 2014; Trier Christiansen 2017). Conversely, the conspicuous success of private metal detecting represents a pressing challenge. The find material has been growing and continues to do so at a speed that leaves little prospect of maintaining an overview – a problem markedly worsened by the decentralised find management system.²

1 Torben.Trier@aalborg.dk

2 The decentralised structure of Danish museums, facilitating close personal contact between museum staff and detectorists, is doubtless a major contributing reason for the success of the liberal attitude towards private metal detecting. Finds are initially handed in to the local museums, which do the basic recording and send off the potential treasure trove finds to the National Museum. However, with limited standardisation of the initial basic recording conducted at the local museums and no complete national database, collecting data for regional analyses becomes excessively time-consuming, if indeed at all possible.

Thus, the possibility of conducting comparative analysis including large parts of the find record is limited. Hence, research focusing on metal-detector finds has unsurprisingly been orientated primarily towards either studies of minor categories of specific types of objects, studies of individual detector sites, or studies of metal-detector finds derived from minor regions. A considerable part of the broad mass of detector finds has neither been studied in detail nor incorporated in comprehensive comparative studies.

The effect of the constraints in hindering comprehensive broad studies is particularly pronounced where such studies are potentially most fruitful, in the most productive regions of Denmark. One of these is the region of the Limfjord, northern Jutland. Owing to a series of excavations at large settlements by the fjord, and not least thanks to the investigations of the largest of the Danish Viking Age ring fortresses, Aggersborg, conducted during the late 1940s and 1950s, the significance of this region during Late Iron Age and Early Medieval times has long been well known (Ramskou 1976; Birkedal Christensen & Johansen 1992; Johansen 1992; Nielsen 2002; Roesdahl, Sindbæk & Pedersen 2014). During recent decades, the tremendous success of the private metal detectorists has contributed to the impression of an elevated level of activity in the region during this period and onwards through the Middle Ages. Hundreds of detector finds continue to be handed in from large settlements situated on the hills around the fjord. Here, as is the case in metal-rich settlements of varying kinds in the rest of southern Scandinavia, brooches dominate the narrowly dated part of the find material from all sites in the region (e.g. Henriksen 2000a; Watt 2000; Fiedel, Høilund Nielsen & Loveluck 2011; Feveile 2014; Wåhlin 2014).

The metal-detected brooches supply a decisive contribution to the dating of the metal-rich sites, and the number of brooches provides a guiding indication of the general level of activity at the sites. However, the reasons for the presence of the often impressive number of brooches are unclear. Some scholars presume that most were dropped during use, an interpretation typically supported by the fact that the majority of brooches seemingly were whole or almost so at the time of disposal/deposition, as indicated by the preserved pin or residues of it, and by the fact that they are usually scattered randomly across the settlements (Vang Petersen 1991: 53; Høilund Nielsen & Loveluck 2006: 73–74; Kershaw 2013: 184). In several other cases, some of the scattered jewellery recovered at large settlements has been interpreted as scrap metal intended for melting and reproduction of artefacts (Hedegaard 1989: 80; Jørgensen 1994: 57; Callmer 1999: 202; Henriksen 2002: 163; Hårdh 2003: 65; Hårdh 2011: 59–61; Høilund Nielsen 2014: 30). Due to the weak contextual support offered by the plough layer for deeper understanding of the phenomenon, explanations as to the reason for the abundance of brooches remain rather speculative. The fundamental loss of explanatory value when the plough first tears the object out of its original context is of course irreversible, and accordingly a detailed understanding of every metal-detected object is unattainable. However, considering the extent and the spread of the

phenomenon, many of these accumulations of brooches are bound to be the product of similar patterns of behaviour. Hence, given a sufficient sample size, such patterns ought to be discernible against the background “noise” left by more random actions. The intention of this paper is to follow this path, and to explore large-scale patterns through diachronic comparative studies of a large corpus of Late Iron Age (c. AD 400–1000) and Early Medieval (c. AD 1000–1150) brooches recovered in the Limfjord region.

In attempt to attain a better understanding of the abundance of brooches, what may be termed a “broad-scale biographic approach” is applied below. The structure of the paper will follow the lifecycle of the brooches, from production to distribution and concluding with use and final deposition. First, however, I will give a brief contextualising introduction to the nature of metal detection in the Limfjord region, and a short presentation of the find record.

Metal detecting in the Limfjord region and the formation of the find record

As in all parts of Denmark, metal detecting in the Limfjord region has primarily been conducted by private metal detectorists, and the brooches included in this study were recovered exclusively by these often highly active and very dedicated hobby archaeologists. The spread of private metal detecting has been surprisingly uneven across the region, and accordingly the number of finds and not least the quality of the find record varies considerably within the region. When metal detecting first boomed in Denmark during the late

1970s and early 1980s, the private detectorists initially started out surveying the areas adjacent to the already well-known large Late Iron Age settlements on the hills in and around Aalborg in the eastern part of the region. They were immediately very successful, and only as finds became sparse at the most yielding sites did they gradually expand their area of interest, soon realising that the neighbouring hills were just as interesting. However, despite the continuing success of the private detectorists in the Aalborg area during the 1990s, metal detecting never caught on in the rest of the region. Apart from the efforts of a few individuals operating in minor regions,³ vast areas in the western and southern part of the Limfjord region remained unexplored by metal detectorists. During the last ten years, this situation has changed radically, and private metal detections have boomed in Thy, at the western end of the region and around the city of Viborg to the south-west.

The differing trajectories of private metal detecting in the eastern and western Limfjord region have left two contrasting find records. To the east, there is a very rich record with, as expected, a high level of geographical coverage, but also a record of finds that have been recorded according to different standards and with varying accuracy over a period of more than thirty years. To the west, we find a more modest but rapidly growing record of finds, recorded in a much more standardised manner during the past ten years and with, not least, a higher degree of spatial precision due to the fact that by far most find locations have been recorded using hand-held GPS. In contrast, only approximately 20 per cent of the eastern finds were recorded using GPS, as the majority of finds were recovered prior to the introduction of this instrument. In addition to this, the standardisation of recording methods in the western and southern areas has been greatly helped by the well-organised detector associations responsible for most of the metal-detecting activity there, in contrast to the eastern part of the region, where metal detecting has traditionally been conducted on an individual basis or by small autonomous groups with varying skills and attitudes to the handling and recording of the finds.

Moreover, recording standards at the museums vary markedly. The area chosen for this study comprises an approximately 15-kilometre-wide zone around the fjord itself, the islands of the Limfjord, and the adjacent areas in the regions of Thy and Himmerland (See fig. 1). To add to the complexity, cultural heritage management in this area is today exercised by no fewer than six local museums, whose data is the prime source of the analysis that follows.⁴ Only two of these museums have followed the same standards of recording and methods, and standards have changed and improved significantly over the years. Not least, photo documentation has improved with the use of digital

3 In particular, in the region around Holstebro, one detectorist was very active from very early on (Helles Olesen 1992).

4 This could of course have been avoided by using only the recordings of the National Museum. However, that would have meant leaving out a considerable number of finds, as these have been recovered within the last few years and thus have not yet been recorded there, not to mention all the more modest finds never sent off to the National Museum.

photography. Still some museums shoot photos only of a few selected objects, whereas the majority today have digital records with photos of all objects.⁵ This last aspect has had a major impact on the present study, since the majority of information has been derived from the records of the local museums and only a fraction of the finds have been studied directly. Twelve per cent has been examined physically. Sixty per cent have been recorded from museum records containing photos of the objects, and data on twenty-eight per cent of the brooches comes exclusively from the written records of the local museums. Furthermore, not only do standards vary, but so do software solutions. Although always digital, the museums have various combinations of databases and GIS software to handle the growing number of detector finds.

The physical check frequently allowed a more detailed description than initially performed at the local museum, but less than 1% of these secondary evaluations lead to decisive alteration of typological character or dating. This is, if leaving aside a few “systematic disagreements” – e.g. the referral of Urnes-style brooches to the Viking Age (previously the earliest of these were thought to stem from the late tenth century (Gjedssø Bertelsen 1994), but today there is little reason to maintain this early date as none of these brooches can be definitely dated this early).

The brooches in this study have been recovered at 111 different sites. Eighty-two per cent of them, however, stem from 16 of the most metal-rich sites, situated within a range of six kilometres of the coast of the Limfjord or to the west and east of the North Sea coast and the Kattegat coast (see Figure 1). Clearly, large areas within the region have never been surveyed; but because information is lacking on the surveyed areas with no finds, any argument relying on negative evidence may be questioned. However, no doubt the concentration of finds in the coastal zone to some degree reflects tendencies of ancient depositional patterns, though likely somewhat exaggerated by the detectorists’ tendency to survey areas in which they have previously been successful.

The metal-detected brooches have almost exclusively been recovered in cultivated fields in the surroundings of existing villages, typically with Romanesque churches testifying to roots at least as deep as the twelfth to thirteenth century. But the majority of the detector sites have been only modestly investigated beyond the surveys conducted by the private detectorists – in many cases, not at all. A few have been investigated through excavations to varying extents, and everywhere the metal finds seem to be connected to plough layers covering settlements or to the fields in the vicinity of these. At a few sites, the remains of burial grounds have also been located in the vicinity of the settlements.

5 Unfortunately, the photo recording conducted at the local museum is in most cases a speedy process involving one frontal picture of each object. Only rarely do the records contain photos of the reverse side of the objects.

To conclude, the record studied here is very heterogeneous and in some respects geographically skewed. This limits the utility of the data. However, in many perspectives, this limitation is compensated for by the size of the record.

The brooches from the Limfjord region

In total, data on 1,859 metal-detected brooches dating to 400–1150 AD has been collected from the local museums in the survey area,⁶ and these brooches thereby represent 9 per cent of all recorded metal-detector finds from the region.⁷ As a consequence of the poor quality of the record, a large proportion of the brooches, those with only a minimum of description and no photo, can only be broadly categorised and dated within the main phases. In contrast to these, a considerable proportion of the brooches dating to the Late Germanic Iron Age and the Early Viking Age can, due to a combination of good recordings and fine chronologies, be dated within even finer timeframes. If we visualise this by dividing the brooches evenly into phases of 25 years within their dating frames, a striking boom during the late sixth century stands out in particular.

Brooches of the Early Germanic Iron Age (AD 400–530)

The Early Germanic Iron Age brooches include 220 whole or more or less fragmented pieces. These brooches represent more than 90 per cent of all metal-detector finds from the region dated to this period. One fragmented relief brooch is made of gilt silver, but the remaining 219 pieces appear to be copper-alloy products; however, one is gilded and another tinned.⁸ By far, the majority are cruciform brooches, and the rest are an extremely heterogeneous group representing several unique pieces (see Table 2).

6 Data collection has been conducted during 2014–15 in connection with an ongoing PhD project. All finds from the entire region recorded at local museums prior to mid-2014 are included. Furthermore, finds from the Vester Vandet site, recorded in the second half of 2014 and 2015, are included. 64 whole or fragmented brooches have been left out of the study owing to poor dating. They are either broadly dated to several of the main periods or to the full period of the study.

7 The total number of recovered finds is far larger, as all detectorists do a rough sorting in field of what is interesting and what is not, as is done by the archaeologists at the local museums prior to recording when the finds are handed in. Despite this process, it is fair to assume that by far the majority of the typically easily recognisable brooches recovered have been recorded. However, small uncharacteristic fragments are probably underrepresented because of this sorting process.

8 The determination of the alloys has predominantly been made through visual inspection conducted by staff at the local museums. As, for example, Unn Pedersen's investigation of the metal finds from Kaupang has demonstrated, this method is highly unreliable, especially in case of the copper-alloys (Pedersen 2015: 74).

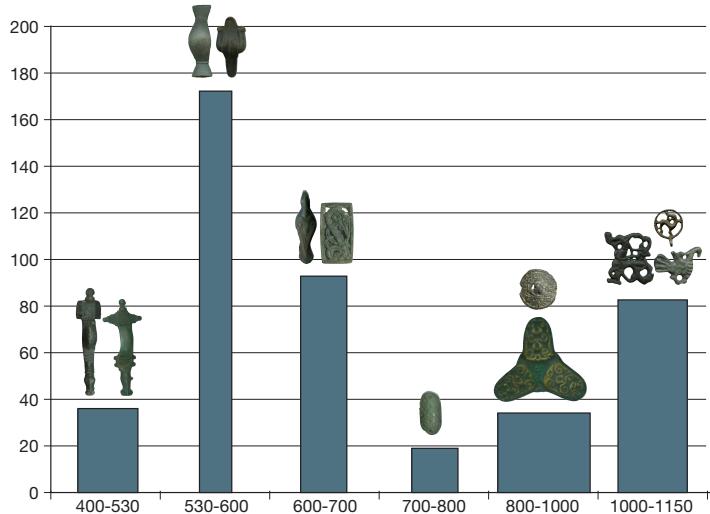

Table 1: Frequency of brooches (per quarter-century) recovered through metal detection in the Limfjord region. The column widths indicate the varying time spans of the periods and the most common brooch types are depicted. Not to scale (Graphics: Louise Hilmar, Moesgaard Museum) <http://files.webb.uu.se/uploader/1338/JAAH--24--Tab--1.pdf>

Total	33	165	23	222

Table 2: Composition of the record of metal-detected brooches from the Early Germanic Iron Age. <http://files.webb.uu.se/uploader/1338/JAAH--24--Tab--2.pdf>

163 cruciform brooches have been recorded in the Limfjord region, and the variance of these is very pronounced⁹ – the poor preservation of the majority of the brooches makes it difficult to evaluate exactly how pronounced. In a modest 23 of 148 cases where the state of preservation can be determined from the records, the brooches are intact – that is apart from the pin construction, which is most often represented only by small patches of rust on any brooch recovered in the rough environment of the plough layer. Frequent types in the Limfjord region appear to be cruciform brooches with round top knobs cast on the head plate and missing, hence probably loose, side knobs (23 pieces – see, for example Figure 2a). Another eye-catching feature is small simple lappets of varying shapes on the sides of the upper end of the foot, present on 13 brooches (see, for example Figure 2b-c).

In western Scandinavia, the cruciform brooch is generally perceived as a main type characterising the Early Germanic Iron Age, and so far, attempts to build a more detailed general chronology for the cruciform brooches have to some degree been unable to overcome the extreme heterogeneity of the material.¹⁰

9 Fragments of brooch feet with animal heads included.

10 The most comprehensive published works on the cruciform brooches was performed by

In essence, a firm framework for a more detailed chronological division of the cruciform brooches is presently not available. Hence, in the present paper the cruciform brooches have all been broadly assigned to the Early Germanic Iron Age.

The remaining group of brooches is, as mentioned, very mixed, and many are probably imports. Three “fake” crossbow brooches with cast imitation of the transverse string by the head of the brooch (See, for example Figure 2d) have most parallels in the Scandinavian part of the Baltic region (Klindt-Jensen, Møhl & Helbæk 1957: 119, Fig. 89.5; Strömberg, 1961: 31, 1b). This may also be in case of three crossbow brooches, however one is an “Ozingell brooch,” a type that in low numbers has been found broadly distributed across large parts of north-western Europe (Hårdh 2003: 52, fig. 4; Schulze-Dörrlamm 1986: 620, fig. 30). Another is a brooch with a very characteristic spiral foot, ending in a bird’s head with curved beak (Figure 2i). No direct parallels to that have been found, but the “Vierknopffibel mit Vogel-Fussplatten” from Thüringen could have been the source of inspiration (Behm-Blancke 1973: taf. 88). Two brooches with rectangular head plates and characteristic spade-shaped feet (see, for example Figure 2e) as well as a fragmented example that must have been almost identical belong to the group of small long-brooches. However, the major part of the heterogeneous material is either unique to the Limfjord region, too fragmented or too poorly described to allow further determination. Noteworthy are an equal-armed brooch with animal heads at both ends, with nearest parallels on Gotland (Fig. 2g), and a gilt “dreirundel brooch” probably inspired by brooches from Thüringen (Behm-Blancke 1973: taf. 110; Nerman 1935: taf. 9, 68).

The brooches of the Late Germanic Iron Age (AD 530–800)

797 brooches or fragments of brooches are dated to this period, and these are almost exclusively made of copper alloys. However, one is of lead, and furthermore 61 are tinned and 20 gilt.¹¹ Compared to the foregoing period, the inventory of brooches here undergoes a radical change. The number of brooches increases dramatically, and the brooches of the region are now almost entirely restricted to a few types well known across most of south-western Scandinavia.¹² The boom and the radical standardisation are particularly pervasive during the initial phase of the period in the second half of the sixth century, underlined by the abundant number of often rather coarse (simple decoration

Reichstein and Bode (Reichstein 1975; Bode 1998), but the broad variety of brooches found in the Limfjord region cannot be fitted into either of their systems of categorisation. Hårdh has also shown that Bode’s system, the most recent attempt to categorise the cruciform brooches, cannot grasp the variance within the cruciform brooches found at Uppåkra (Hårdh 2003). See also (Høilund Nielsen 1984).

11 These figures can clearly only be expected to be a rough guide, as the initial recordings of the local museums occasionally omit to mention tinning and gilding even when actually present – sometimes simply because it is not visible before a thorough cleaning of the object, which in most cases is carried out in the National Museum.

12 The division has been conducted primarily according to Karen Høilund Nielsen’s types, based on a simplification of Mogens Ørsnes’ thorough work from the 1960s (Høilund Nielsen, 1987; Ørsnes, 1966).

and often rough surface) small equal-arm brooches and the beak brooches (see Table 3). However, within the main types, variation is considerable regarding shape, size and decoration. Less frequent in the early phase are the circular plate brooches with simple stamp decoration or furrows, and S-shaped plate brooches. The latter group is perhaps the most varied, and in addition to ten copies of Karen Høilund Nielsen's (KHN's) commonly known type L1a, this group comprises at least 12 double-headed L1b S-shaped brooches of varying forms. Several of these have vaguely marked heads and a more oblong oval outline (see, for example, Figure 2p-q), presumably reflecting a gradual transition to the oval plate brooches with the twin snakes biting their bodies – a type very common in the region (Høilund Nielsen 1987).

<http://files.webb.uu.se/uploader/1338/JAAH--24--Fig-2.pdf>

During the later phases, this strict standardisation is relaxed. The brooches still belong to a few standard types – in the seventh century mainly oval and rectangular plate brooches and bird brooches – but shape, decoration and quality vary profoundly. Despite variation, the extremely coarse impression left by the poorest of the sixth-century brooches now seems to be gone.¹³ One feature that underlines the diversity is the finish of the surface of the brooches. Gilding and particularly tinning is increasingly popular. Whereas in the preceding decades only a few selective brooches, primarily S-shaped and circular plate brooches and the luxurious button-on-bow brooches, were extraordinarily prepared in this manner, now this way of secondarily improving the look of the cast brooches is becoming fairly common. However, as previously noted by Henriksen and Gramtorp, this extra refinement of the surface is mainly restricted to a few types (Gramtorp & Henriksen 2002) – in the Limfjord region, predominantly to the rectangular and oval plate brooches and the bird brooches. The use of gilding is especially biased, as more than 70 percent of the Late Germanic gilt brooches that can be determined are rectangular plate brooches. Moreover, the more heterogeneous picture left by the seventh-century brooches is enhanced by the presence of a few horse- and swan-shaped plate brooches of individual character.

The eighth century is characterised by a remarkable decrease in the number of brooches. These are mainly various kinds of domed brooches, and by far the majority consist of small tortoise brooches. Many are severely corroded, but the general impression is one of profound variation. However, the group does contain at least four very similar brooches of KHN type N1e, characterised by an interlaced single or double line at the centre of the brooch (see, for example Figure 2ae-af).¹⁴

Finally, a few brooches dated to this period appear to be foreign in origin. However, imported jewellery in the Late Germanic Iron Age seems to be restricted to interregional Scandinavian products. Three domed circular brooches (KHN type M) have most parallels in northern Scandinavia (Ørsnes 1966: 148), and a series of different brooches apparently originate in south-eastern Scandinavia. This is definitely the case of a Gotlandic animal-head brooch, and a circular openwork brooch (KHN type S2C) and a snake brooch (Figure 2r) of KHN type L2A probably represent imports from around the same region too (Arrhenius 1960; Høilund Nielsen 1991; Nerman 1969-75).

13 Coarser brooches did actually exist. Several simple rectangular brooches made of iron covered by a thin copper-alloy plate have been found during excavation at some of the sites and seem to have been rather common (Mikkelsen et al 2008: 81–82; Nielsen 2002: 206, fig. 8C; Sarauw & Trier Christiansen 2014: 132, fig. 6D). However, these are never recovered by the private detectorists, who discriminate between alloys and only very rarely (most often only accidentally) investigate iron signals.

14 Martin Rundkvist, who has most recently studied the small tortoise brooches, has termed these N1e variant 2 and 3 (Rundkvist 2010: 143).

The brooches of the Viking Age/ Early Middle Age (AD 800–1150)

The find records contain 840 brooches or brooch fragments dated to between the ninth and thirteenth century. 798 are copper-alloy pieces, and 27 of these are recorded as tinned, another 54 as gilded. The record also contains 33 silver brooches or fragments of such, and the majority of these are large, high-class Urnes-style brooches.¹⁵

15 An additional three are recorded as possible silver objects.

Although the Viking Age material from the ninth and tenth century comprises a wide range of brooches often few in number, the record is dominated by a few main types of which the trefoil, the small circular brooches decorated with Borre-style animals or interlacing, and the equal-armed brooches are by far the most frequent (see Table 3). The brooches within these categories vary considerably. However, proper categorisation and comparison is, especially in the case of the equal-armed brooches, not possible for large parts of the material due to pervasive fragmentation. Even basic estimation of the original number of brooches is a challenging task. Only one of the equal-armed brooches is recorded as intact, and most of the fragments are small, broken-off ends of the brooches.

Despite this variation, particularly the trefoil brooches reveal some level of standardisation, as fairly small, similar brooches with simple geometric ornamentation belonging to Maixner's type G group are very frequent (30 pieces) (Maixner 2005). Once again, detailed comparison is difficult as the trefoil brooches too are most often in a poor state of preservation, typically being represented only by broken-off lobes or the massive triangular centrepiece.

The brooches of the eleventh and twelfth centuries are dominated by four main types, within which there is some variation. Despite this, the general impression left by the record is one of markedly increasing standardisation. This is an impression probably enhanced, to some degree, by the large numbers of some of the brooches compared to the frequency of brooches from the preceding centuries.

The Urnes brooch or Urnes-style brooch – whose name is slightly misleading as some pieces are actually depicting Mammen-style and Ringerike-style animals (Gjedssø Bertelsen 1994) – is by far the most heterogeneous group. Style and quality as well as size vary, from small, crude pieces with animals so stylised that they are hardly recognisable, to large, often silver or tinned/gilt copper-alloy top-class pieces with elaborate and detailed ornamentation. Even the basic form of the Urnes-style brooches varies, as a small group of these are not made of a network of threads of animal extremities but are simpler copies made as openwork plate brooches. The latter group consists of 13 profoundly similar pieces depicting Mammen/ Ringerike-style animals (see, for example Figure 3k);¹⁶ five other slightly atypical brooches of varying forms but all characterised by a distinct S-shape appear related to these plate brooches.

In contrast, the small openwork circular animal brooches of the Aalborg group (see, for example Figure 3ac) display an almost extreme uniformity, as already noted by Gjedssø Bertelsen in the early 1990s. When she presented her study, a modest 29 copies of this brooch had been recovered across Denmark. Today, detectorists have handed in 82 from the Limfjord region alone.¹⁷

¹⁶ My thanks to Else Roesdahl and James Graham-Campbell for comments on the animal styles.

¹⁷ The number is probably somewhat higher, as some museums have not distinguished between these and the related Lamb of God brooches.

However, in this case the general impression presented by Gjedssø Bertelsen in the 1990s remains unchanged (Gjedssø Bertelsen 1992). The Aalborg group animal brooches do appear extremely abundant in the Limfjord region, and most of them appear so uniform that it seems likely that they were

produced in one or a few workshops in the region, or were produced from copies of a few models. The only noticeable variation is the imitated beaded rim of a few pieces.

In addition to the brooches of local Scandinavian character, the record also contains a series of imports from more distant areas during the Viking Age and the Early Medieval Period. Most common are the many different small disc brooches of Carolingian-Ottonian type (see, for example Figure 3r-v), which seem to indicate intensive connections to north-western continental Europe (e.g. Bastrup 2005; Frick 1993). The number and spread of these suggests that they were worn frequently, which signals a markedly changed attitude towards foreign jewellery compared to the preceding centuries. Unfortunately, the number of these recovered in a dated context is very modest. Hence, they are in most cases very broadly dated from the ninth to the late twelfth century, and the time of their introduction in Denmark is therefore uncertain.¹⁸ However, the absence of such brooches in the find-rich early ninth-century layers of Ribe seems to suggest that the flow of these brooches to the north did not, at the earliest, start until the second half of the ninth century (Feveile 2011: 151).

Production and distribution of brooches in the Limfjord region

Detectorists have recovered the possible traces of non-ferrous workshops in the form of little bits and pieces of melted metals at many sites scattered across the region, and a few of the numerous excavations carried out at the settlements in the region have also yielded traces of non-ferrous metal workshops (See Figure 5). However, apart from the obvious conical pieces of spillage from the casting process, the little bits and pieces of melted metal may not actually represent waste from workshops, still less production of jewellery, and they are, moreover, impossible to date when derived from sites typically characterised by find material dated with general dating frames stretching over millennia. This latter problem also applies significantly to the find material from the excavations, as this consists exclusively of broadly dated finds such as raw materials, waste products, and crucibles. More direct evidence of the production of specific types of jewellery in the form of moulds with recognisable negative imprints of the cast objects is absent - probably in some incidents due to coarse excavation methods. Additionally, perhaps, owing to systematic recycling of the moulds and the use of an organic component in the moulds, as suggested by Hedegaard (Hedegaard 1992: 80–81). In addition to these scarce and merely indicative sources and the general impression left by the abundant number of brooches, a few somewhat firmer observations

¹⁸ Enamel brooches with a cross motive have actually been recovered south of Denmark in datable contexts. These seem to belong in the ninth and tenth century. The remaining types are more broadly dated (Bastrup 2005; Frick 1993).

pointing to the actual production of brooches in the Limfjord region can be derived from the record of the metal-detector finds.

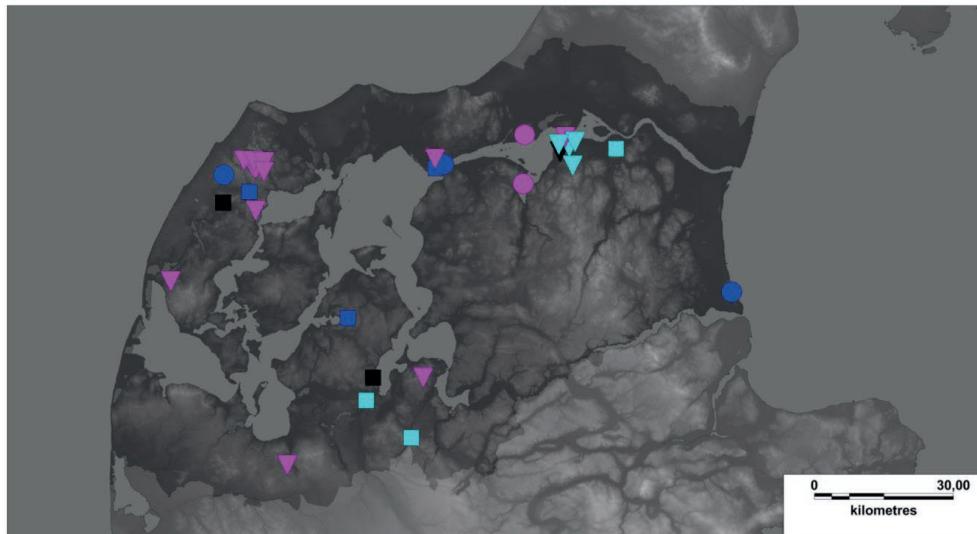

Figure 4: Distribution of traces of non-ferrous workshops and traces of production of brooches. Production in the Early Germanic Iron Age

None of the brooches dated to the Early Germanic Iron Age are recorded as showing indications of being unfinished, and traces of the production of brooches in this period have not been found in the Limfjord region.¹⁹ Yet given the number of brooches, a widespread production across the region appears to have been likely. A more thorough investigation of styles and technical details of especially the cruciform brooches may potentially reveal interregional differences. That is, however, not possible solely on the basis of the often rather coarse records of the local museums. On the other hand, the pervasive variation of the material seems to follow the general trend of the period, and perhaps the mixed impression points to mobile or at least highly communicative craftsmen, who have been suggested by several scholars to be prevailing in these centuries (e.g. Carnap-Bornheim 2001; Hines 1997: 222; Pedersen 2015: 45).

Actually, one find directly pointing to the presence of non-ferrous craftsmen in this period has been recovered in the region – a matrix for the production of D-bracteats. This has been recovered at the Postgården site adjacent to Sønder Tranders, near Aalborg to the east (Johansen 1992: 85).

¹⁹ Five brooches show more or less pronounced signs of secondary exposure to heat. However, this could just as well be the effects of a funeral pyre as signs of melting for reuse of the metals.

Production in the Late Germanic Iron Age

Indisputable traces of the production of brooches are also sparse in the find material from the Late Germanic Iron. However, numbers are increasing and distribution patterns suggest the existence of local workshop environments. At Øster Vandet in the western end of the region, detectorists have recovered a patrice for the production of gold foil figures dated to around AD 600. In addition to this, the record of finds from the late sixth century and the following centuries, the Late Germanic period, contains a few finds indicative of the production of brooches. At Nørholm to the east, the most productive of the detector sites in the region, detectorists have recovered two unfinished beak brooches (Figure 6a–b) and a miscast small tortoise brooch. Finally, the neighbouring site, Sønderholm, has in addition yielded a beak brooch that was probably miscast.

Furthermore, several types of brooch from the sixth to eighth century display more or less skewed distribution patterns, indicating interregional variation of preferences and probably also variance of production. The site Øster Vandet in Thy in the north-western part of the region has yielded seven of a total of 26 circular plate brooches (see, for example, Figure 2s) found in the region, and a further three more badly corroded pieces probably belong to the same category. One fragmented piece is of lead, which is highly atypical. Rust on the reverse side indicates that a pin was at some point mounted on it, but this may just represent the last final use of an older model for the production of these circular brooches. However, the later rectangular and oval plate brooches display the most biased distribution patterns. These are clustered in the eastern part of the region, the seventh-century oval plate brooches to such an extent that all 57 recovered by metal detection in the region so far have appeared at sites to the east (Fig. 5).²⁰ An additional two found during the excavation of pit-houses at the Bejsebakken site strengthen this biased distribution pattern (Sarauw, forthcoming: 147). Two possible fragments of oval plate brooches recovered at the detector site Vester Vandet and one found during the investigation of the Trabjerg settlement towards the south-west are the exceptions that confirm the rule (Bender Jørgensen & Eriksen 1995: 46, Fig. 28). This extremely skewed spread may to some extent be the product of varying conditions of preservation at the sites, as many of the sites in the western end of the region have thick well-preserved cultural layers in which the seventh- and eighth-century deposits typically constitute the oldest and hence best-protected layers.

20 Two small fragments, one found at Vester Vandet and one recovered at the Øster Vandet site in Thy, might also be fragments of oval brooches. Nevertheless, it cannot be ruled out that the fragments belong to S-shaped brooches.

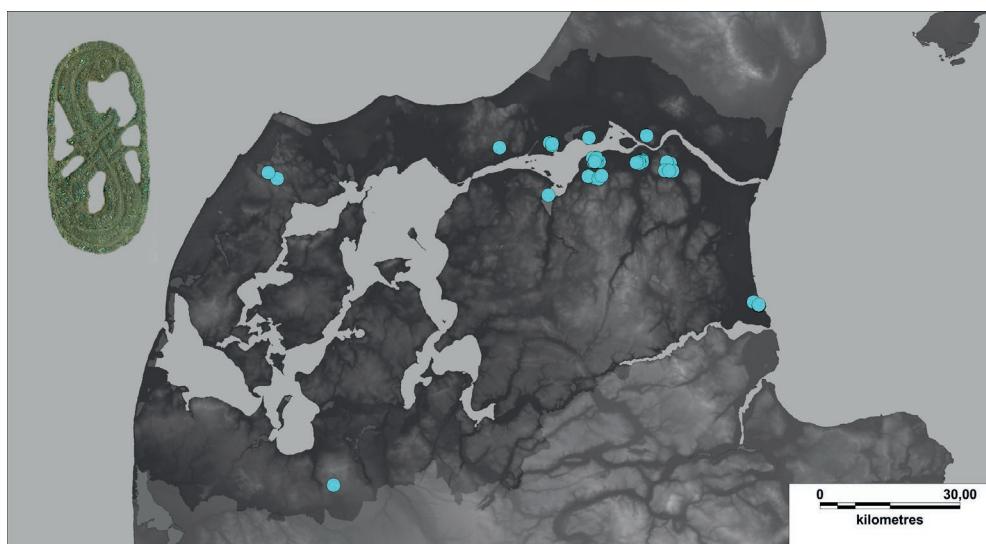

Figure 5: Distribution of oval plate brooches (KHN type J) in the Limfjord region (Graphics: Kirsten Bach Larsen, Nordjylland Historiske Museum) © Geodatastyrelsen. <http://files.webb.uu.se/uploader/1338/JAAH--24-Fig--5.jpg>

Brooches from these centuries may thus be somewhat underrepresented in the record. Yet the skewed distribution appears so marked that, to some degree, it must reflect patterns formed during the Late Germanic Iron Age. Above all, it contributes to a general impression of diverging developments in the east and at the western end of the fjord, involving what appears to be the ascendancy of a productive and innovative non-ferrous workshop environment during particularly the seventh century in the eastern part of the region. In the western part, by contrast, production seems to have decreased and the range and quality of brooches to have been modest. However, the extent of this decrease is highly uncertain. Not just the fact that disproportionately many brooches in the western part of the region may still be in situ in preserved cultural layers, but also varying local environmental conditions may have skewed the record. As is demonstrated below, preservation conditions are seemingly poorer at the sites to the west closest to the North Sea, which may have severely affected the typically highly fragmented plate brooches of the Late Germanic Iron Age.

In general, the abundant Late Germanic brooches, especially the numerous equal-armed and beak brooches, clearly invite future and more detailed analysis of local networks in relation to issues concerning both production and use of the brooches; again, however, that would require a better record than that delivering the information for the present study. In fact, Vang Petersen has already pointed to three brooches from the Bejsebakken site that are so similar that they were probably made from the same model, a strong indication that they were actually produced here (Vang Petersen 1991: 55).

Figure 6: Evidence of production and repair of brooches: (a–d) misasts, (e) rectangular brooch with rivets after the repair of the pin construction, (f–h) models for brooch production. a) Cat. no. 767, b) Cat.no. 231, c) Cat.no. 1855, d) Cat.no. 1567, e) Cat.no. 932, f) Cat.no. 1862, g) Cat. no. 1861, h) Cat.no. 1860 (Graphics: Louise Hilmar, Moesgaard Museum) <http://files.webb.uu.se/uploader/1338/JAAH--24--Fig--6.pdf>

Production in the Viking Age

Moving on to the Viking Age, evidence for the production of brooches in the Limfjord region is modest. Finds from the first half of the ninth century are lacking, but three master models for the production of disc brooches with Borre Style interlacing motifs have been found in three different sites. Interestingly, that corresponds to the impression left by the brooches found in the region, as next to the trefoil brooches these are the most common type of brooch here. The small circular brooches therefore most likely also represent the best basis for tracing interregional differences during this period. Unfortunately, the studied records lack detailed information of almost one-third of these, leaving only a fragmented overview of this group of brooches. However, the small circular brooches are distributed across the entire region, and the general impression left by the 46 of which there are photos is one of a strikingly rich variation. Possibly the profound variation is due to the mode of production, which to judge from the rather coarse models found must have involved some element of additional decoration, probably done individually by hand in wax models, as suggested in connection with the production of the tortoise brooches (Lønborg 1999).

A few Viking Age brooches appear so similar that they were probably made from the same model. Particularly noteworthy is a disc brooch with a distinct, interlaced geometric pattern covering the full surface. Two copies, which are virtually identical and must have been produced from the same model, have been found at Nørholm in the eastern end of the region, and a third one was recovered during excavation of the neighbouring settlement, Bejsebakken, in the late 1990s (Sarauw & Trier Christiansen 2014: 132, Fig. 6B). This surely suggests that these were most likely produced somewhere in the eastern part of the Limfjord region. Another has been found in the province of Groningen in the Netherlands, testifying to the widespread networks in which the population of the Limfjord region was engaged.²¹

Production in the Early Medieval Period

The most widespread and numerous indications of brooch production are to be found among finds from the eleventh and twelfth century. Six of the abundant Urnes-style brooches have defects from the casting or appear never to have been finished. In addition to this, a lead model for the production of these brooches was found at Sebbersund in the early 1990s, and another possible model has been recovered at Øster Vandet, the most productive site to the west. Furthermore, the Sebbersund site has also yielded a model for the production of small circular animal brooches related to that of the Aalborg type (Gjedssø Bertelsen 1992: 251, Fig. 17). The record also contains six unfinished or miscast Urnes-style brooches (see, for example Figure 6c–d), a miscast openwork animal brooch from the Early Medieval Period, and at least one additional brooch which was never completed, as it was still housed in a piece of the mould. All were found scattered across the region. Finally, a coarse openwork lead disc may be a model for brooches related to the openwork brooches of the local Aalborg type.

The widespread evidence of brooch production may indicate an increase of local brooch production during the eleventh to twelfth century. At the same time, the abundant brooches are characterised by a marked standardisation, as mentioned earlier. Despite this, the Urnes-style brooches and bird-shaped brooches in particular show some variation and several distinct subtypes are distinguishable. However, these generally seem widely distributed across the region, suggesting an intensive flow of ideas and probably also of finished products between the settlements in the region.

Finally, several brooches show traces of repair. The most prevailing evidence of repair is one or two rusty rivets visible at the ends of the brooches on the front side or holes obviously intended for riveting (see, for example Figure 6e). The rusty rivets are in most cases the result of the mounting of a new pin construction, and this rather coarse mode of repair is almost exclusively restricted to the brooches of the sixth to eighth century.

21 Stored in the Noordelijk Archeologisch Depot number G2008-II.31b. (My thanks to Nelleke IJssennagger –Fries Museum / University of Groningen, for information on the piece)

Discussion: the development of brooch production in the Limfjord region

To conclude, the abundance of brooches recovered in the Limfjord region seems to suggest that the production of brooches may have been a prevalent phenomenon across the region throughout the period AD 400–1200. The character, the scope and the frequency of brooch production are difficult to infer from the record. Thorough physical studies of the brooches, especially the backs of the objects, would no doubt shed light upon many details that are not possible to detect during a pilot study such as this. However, the varying quality of both finished and the few unfinished brooches, and the varying types of alloys worked, seem to suggest a rather varied production. The best evidence of the scope of production at the individual sites is supplied by the few excavated workshops. Apart from the evidence from the crafting and trading site at Sebbersund, which appears to signal production on a scale that implies the intention of sale to a broader market (Birkedal Christensen & Johansen 1992), the small workshops recovered at the other sites in the region seem to suggest a modest production, predominantly produced for local consumers and for a market that rarely stretched much beyond the limits of the neighbouring villages. However, the majority of the sites with small workshops have only been partly excavated, which leaves the possibility that at least some of these are parts of larger workshop areas.

In total, this is a varied and widespread production, and one which corresponds well with the results of a survey presented by Ulriksen in 2002 demonstrating that traces of non-ferrous metal work were present at almost one-third of agrarian settlements investigated in Denmark,²² as well as with the general impression of the mode of production presumed to have existed during the Viking Age put forward by several scholars in recent years (Maixner 2005: 64; Gustafsson 2013: 87–88; Kershaw 2013:132–133).²³

Of course, the broad long-term perspective presented here obscures chronological variations. There are actually several indications of changing modes of brooch production. From the remarkable change in the quality and not least number of brooches from the fifth century and the opening decades of the sixth century to the second half of that century, one might infer a development involving the change from relatively few but high-quality products to the appearance of a dramatically booming number of often rather coarse small equal-arm brooches and beak brooches. The decreasing quality and increasing number of brooches appearing during the sixth century may reflect a situation characterised by a booming local production, carried out by a growing number of craftsmen with varying skills, as earlier suggested by Hedegaard (Hedegaard 2002: 46). On the other hand, the number of similar brooches recovered in the Limfjord region implies some level of mass

22 Survey based on published information of a selection of 25 sites excavated in recent years with modern methods (Ulriksen 2002).

23 See also Hedegaard's discussion of the different modes of production in Late Iron Age Scandinavia (Hedegaard 1992).

production, at least at some sites. This mode of production has also been suggested by Hedegaard's studies of production of the related beak brooches (Hedegaard 1989).

During the seventh century quality increases markedly again, suggesting perhaps a smaller but more skilled number of craftsmen handling production. Moreover, it is tempting to see marked interregional differences of brooch distribution as an indicator that the craftsmen were fairly stationary, even though it can of course never be completely excluded that the brooches were produced by mobile craftsmen simply responding to local preferences. The latter appears more likely during the Viking Age, as the scattered master models indicate a scale of production beyond what it must have been possible to sell locally. Yet the models may also have been the tools of local sedentary craftsmen producing with the intention of selling their product to a broader range of consumers, for example at one of the large central trading places at Ribe, Kaupang, or Hedeby in the neighbouring regions. Such a mode of production and distribution would not necessarily exclude that a large proportion of the jewellery in circulation were in fact produced in innovative and highly productive workshops in the Viking Age towns which several studies seem to suggest (e.g. Drescher 1983; Fuglesang 1987: 219; Sindbæk 2011). However, we must also expect a certain element of local production; a fact also pointed out by Fuglesang (Fuglesang 1987).

Finally, the pervasive standardisation of the eleventh- and twelfth-century brooches could indicate mass production in a few sites. However, miscasts and unfinished brooches have been found widely scattered across the region. The widespread indicators of brooch production may indicate an intensification of local brooch production. Nevertheless, if we are to trust the distribution patterns of the brooches, which appears to signal a marked unification of brooch inventory across the region, local production has been greatly influenced by general stylistic trends perhaps coming out of a few larger workshops. The few high-class Urnes-style brooches that contrast with the pattern of standardisation were probably produced at these workshops. The urban centres under development at Aalborg and Viborg would have been the likely base of such trendsetting environments.

Use, reuse, and deposition of brooches in the Limfjord region

When the reasons for the abundance of brooches at the settlements have been touched upon, the arguments have predominantly rested on two categories of observations. First, on spatial observation, such that a widespread distribution is linked to randomness, and accordingly to the notion of accidental loss. Second, on observations regarding the state of the brooches, such that either signs of deliberate breakage or high general fragmentation have led to the

conclusion that a large proportion of the brooches found at some sites were probably scrap pieces intended for recasting – lost or deposited in workshop areas. Conversely, other scholars have emphasised indications that a large proportion of the brooches found in different areas were intact on entering the soil, indicating accidental loss or perhaps even deliberate deposition. In the following, we will investigate whether some of these assumptions may also be valid in the Limfjord region.

Brooch fragmentation and the circulation of scrap metals

In the early 1990s Peter Vang Petersen presented a study of the increasing amount of find material from the Late Germanic Iron Age recovered all over Denmark, in which he argued that most of the brooches were probably either accidentally lost or deliberately deposited in the soil. He pointed to the fact that 88 percent of the brooches with preserved pin-lug showed traces of rust, indicating that the pin was still in place and the brooches probably intact when they entered the soil. This, moreover, implied that the fragmentation of many metal-detected brooches had been caused by processes of attrition inflicted by cultivation (Vang Petersen, 1991: 53). In contrast, other scholars have interpreted the pervasive fragmentation of brooches from sites such as Uppåkra, Kaupang and Stavnsager as indications of metal workshop areas in which large numbers of old scrap pieces were circulating (Callmer 1999: 202; Høilund Nielsen & Loveluck 2006: 73–74; Høilund Nielsen 2011: 314; Hårdh 2003: 64; Hårdh 2011: 59–61; see also Maixner 2015). However, why is so much scrap metal *deposited* at the sites? This intriguing question is never really addressed by scholars who maintain that the fragmented brooches, or at least a considerable part of them, were scrap metals. The fact that the brooches were scrap products could, of course, have led to more careless handling of them, which potentially resulted in more spills. Nevertheless, precisely the fact that the metal was considered a resource worth collecting speaks against this – a fact that is further underlined by the chronological composition of the record. The brooches are thus most abundant during the Late Germanic Iron Age, when metal supplies appear to have been particularly short (Jouttiärv 2002). The jewellery could of course have originated in scrap depots hidden by the craftsmen. However, had this been a commonly practised strategy, such scrap depots would probably have been recovered more frequently.²⁴ The existence of regular scrap stocks would likely also have produced marked clusters of unfinished or chopped-up artefacts, which are so far absent in the Limfjord region despite the efforts of the many busy metal detectorists. On the other hand, it could be argued that in a period characterised by increased use of scrap metal, an increase in scrap pieces at

24 To my knowledge, no such deposits have been found in Denmark. On the contrary, at the Danish site with the richest evidence of non-ferrous metal workshops, Ribe, it has been noted that copper-alloy objects were surprisingly few, even in waste layers otherwise full of traces of metalwork (Frandsen & Jensen 2006: 30). However, a few good examples of scrap metal depots have been uncovered in neighbouring countries (e.g. Jørgensen 1994: 58, fig.7; Gustafsson 2011)

production sites, as well as increased spillage of this type of raw material, would be expected. However, in the author's opinion, this contradicts normal economic behaviour at a time of shortage.

There seems to be broad consensus that cultivation is to be regarded as a major contributing factor to the attrition and fragmentation of plough-layer metal finds. Documenting the effect is, however, an extremely delicate matter. The optimal solution for evaluating the level of attrition caused by cultivation would no doubt be the comparison of a large corpus of brooches recovered from in situ contexts at one site to a large number of brooches recovered from the plough layers covering the same site, and in addition to this, preferably of the same type of brooch. The number of brooches recovered through excavations at the settlements in the Limfjord region is unfortunately far too modest to form a firm statistical base for such studies. The brooches from the Bejsebakken site, the excavated settlement having yielded most brooches in the region, may give a vague hint of the effect of the stay in the plough layer. Here, fourteen copper-alloy brooches were recovered in pit-houses during the extensive excavations in 1999 and 2000. Additionally, 161 contemporary brooches had been recovered from the plough layer by private detectorists prior to the excavation. Half of the brooches found in situ were fragmented, whereas 76 per cent of those from the plough layer were more or less damaged.²⁵

The level of fragmentation varies greatly according to the general shape of the brooches. Thus, comparison is clearly strengthened if it is made between brooches only of similar kinds. The Late Germanic rectangular brooches were the most frequent type of copper-alloy brooch recovered during the excavations at Bejsebakken. Four were found during the investigations, and another 15 through metal detection of the plough layer. Half of the rectangular brooches found in situ were fragmented, whereas this was the case for two-thirds of those that were recovered through metal detection.²⁶ Relying on numbers this low, the result is questionable. However, through comparison of objects from excavations and plough-layer metal-detector finds from the Lundsgård site on Funen, Henriksen has demonstrated the same tendencies (Henriksen 2000b: 19).

Another feature of the excavated brooches from Bejsebakken that differs markedly from the metal-detected brooches is the general preservation of the surface, which is significantly better on brooches that never entered the plough layer.²⁷ If comparing the general preservation of the surface of the brooches recovered through metal detection in the Limfjord region to the level of fragmentation,²⁸ there appears to be a distinct relationship between the degree

25 131 of the metal-detected brooches were followed by sufficient data to evaluate the state of preservation.

26 Data on the level of fragmentation only available for 12 of the brooches.

27 Half of the 14 brooches found in situ had well-preserved surface (according to the definition in note 27).

28 1 214 brooches were followed by sufficient data to evaluate both variables (fragments of same brooch only counted as one). Surface variables: well-preserved surface = less than 10% of surface corroded. If gilded or tinned, at least two-thirds of the secondary surface treatment still preserved. Inlays may be fully or partially missing; partially preserved surface = more than 10%

of fragmentation and the degree of surface degradation (see Table 5). Assuming the state of the surface to be a rough guideline of the level of attrition to which the brooches have been exposed, this also seems to imply that pervasive fragmentation is linked to the general state of preservation and clearly affected by the stay in the plough layer rather than being the result of pre-depositional events.

	Whole	Large fragment	Small fragment	Total
Well-preserved surface	107	55	24	186
Partially preserved surface	319	218	180	717
Degraded surface	104	131	103	338
Total	649	479	388	1,241

Table 5: Fragmentation and surface degradation of brooches from the Limfjord region.
<http://files.webb.uu.se/uploader/1338/JAAH-24-Tab--5.pdf>

One of the factors that is generally problematic to handle is the effect of time. Given the processes of attrition active in the plough layer, the general state of preservation of the metal-detected objects must also to some extent reflect the duration of the stay in the plough layer. This important factor is difficult to study and document properly, as other decisive variables may have affected the formation of the record of metal-detected finds over the years. First of all, it is impossible to assess when an object was pulled out of the original context and into the plough layer. Secondly, equipment has improved and the detectors of today can detect smaller and thinner objects than their predecessors (e.g. Moesgaard 2012: 115). Thirdly, the chances of recovering an object improves with increasing size, meaning that assemblages from sites metal-detected over a period of many years will under ordinary circumstances reveal a tendency towards increasing fragmentation of the recovered finds (e.g. Dobat 2010: 149). Haldenby and Richards, who have studied the attrition of plough-layer metal finds from Britain, have overcome the latter two issues by, in the first place, studying only the finds from sites surveyed by the same detectorists using the same metal detectors for two decades, and in the second place, focusing on the state of certain types of pin which, in terms of detectability are affected only modestly by fragmentation. It is perhaps not surprising, but nevertheless important, that these studies have demonstrated that fragmentation increases during the stay in the plough layer (Haldenby & Richards 2010).

of surface corroded but parts of original surface still preserved; degraded surface = rough and corroded across entire surface. All fine ornamentation and secondary surface treatment gone. Fragmentation variables: Whole = intact – but pin may be missing; large fragment = > half; small fragment < half.

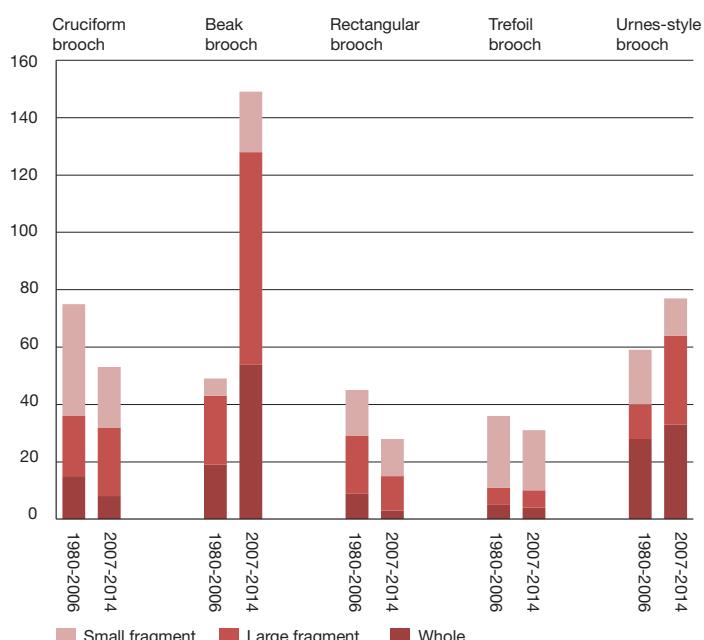

Table 6: Development of fragmentation of some of the most frequent types of brooch.
<http://files.webb.uu.se/uploader/1338/JAAH-24-Tab-6.pdf>

The tendency towards growing fragmentation is roughly discernible in the find record from the Limfjord region. If we compare the development of fragmentation of some of the most frequently found brooch types, the ratio of fragmented to intact brooches has in most cases increased during recent years, but only by between 1 and 9 per cent (see Table 6).²⁹ What is much more markedly illustrated by the mapping of fragmentation is the striking variation in preservation between the different categories of brooches. Only around 55 to 60 per cent of the beak brooches and the Urnes-style brooches are fragmented, whereas among the rectangular plate brooches and trefoil brooches approximately 15 per cent are intact.

The Early Germanic cruciform brooches recovered during the most recent years break this pattern as they are in slightly better condition than those recovered prior to 2007. This probably reflects the fact that general studies (as presented in Table 5) disguise variation due to local conditions, with soil acidity and the different strategies of cultivation practised being important parameters.³⁰ The most profound differences in the general state of preservation are to be found between the poorly preserved brooches from sites closest to the North Sea coastline to the west (Vang and Vestervig), where soils are sandy, and the better preserved ones in the central part of the Limfjord region, situated on the chalky hills of Nørholm/Mellemholt and Øland. This contrast suggests that local environmental conditions have affected the metal finds quite radically. Table 7, which illustrates this, includes all brooches

29 Fragments of the same brooch only counted as one (the largest piece counted in). Thirteen plate Urnes-style brooches were excluded to avoid biasing due to their fundamentally differing shape. For definition of levels of fragmentation, see note 27.

30 In the most extreme cases, the effect of differing local conditions can be detected with single objects, as illustrated by the partial degradation of a bird brooch from Søgård in Thy (THY 6135X1). Half of the front of this brooch is well-preserved, whereas the other half is completely deteriorated.

found at the sites between 2006 and 2014; when these are narrowed down to specific types, the varying degree of fragmentation between the different sites becomes even more apparent. At Vestervig only one in eleven cruciform brooches is intact and seven are categorised as “small fragment,” in contrast to the cruciform brooches from Nørholm, where five of 14 are intact and only four are “small fragments.” Such variation could potentially generate seriously misleading results from an uncritical comparison of assemblages from different sites, as well as during comparative studies of different types of objects found at same site. The cruciform brooches, other bow brooches and large thin brooches like the Late Germanic plate brooches, together with the tortoise, equal-arm and trefoil brooches of the Viking Age, are the types of brooch that might be expected to have suffered most severely from harsh conditions.

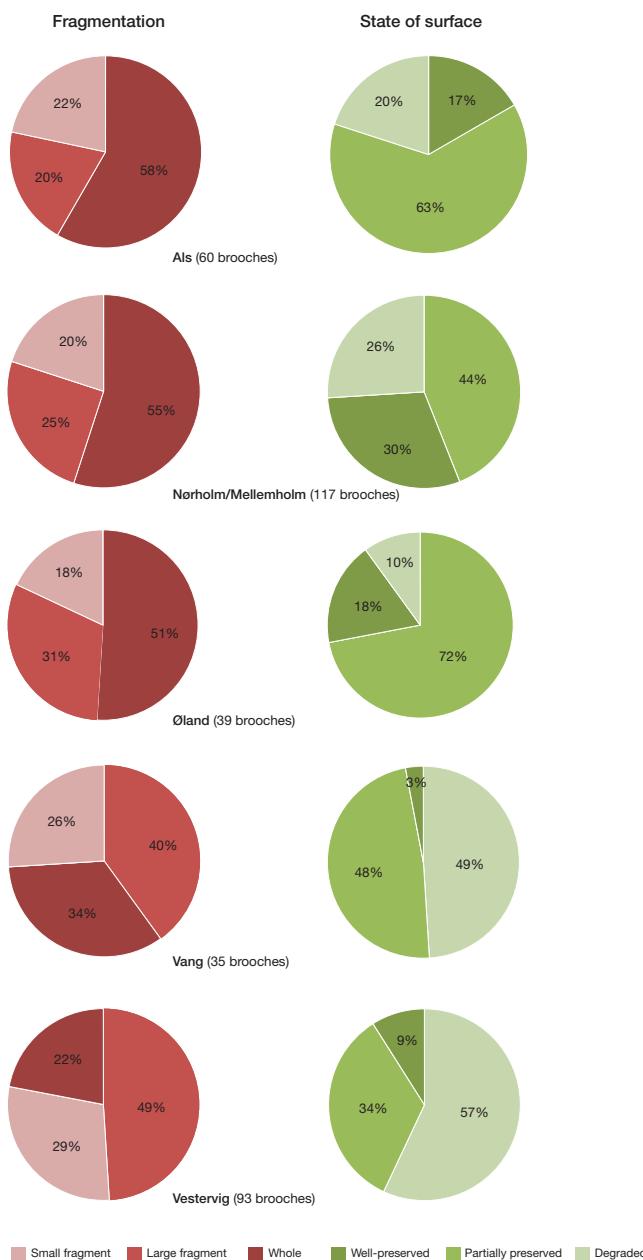

Table 7: Fragmentation of brooches recovered at selected sites since 2006. Note the poor preservation of the brooches found at the western settlements (Vang and Vestervig) where soils are sandy, which contrasts with the state of preservation of the brooches found in the central part of the region (Øland and Nørholm) characterised by chalky soils.
<http://files.webb.uu.se/upload-er/1338/JAAH--24--Fig--7.pdf>

Although the analyses presented here seem to suggest that breakage of the brooches stems to large extent from processes active in the plough layer, the recycling of scrap metals must have been frequent in Late Iron Age and Medieval Scandinavia. Jouttiäärvi's comprehensive study of the composition of copper-alloy objects showed a marked increase in the use of scrap metals in the period between the fall of the western Roman Empire and the beginning of Viking Age around AD 800 – a development which is clearly linked to insufficient supplies of fresh raw materials due to political instability and disruptions to mining (Jouttiäärvi 2002).³¹ Furthermore, a long list of other finds and observations indicates that scrap metals were an important resource in Scandinavia during these centuries (Callmer 1984; Jørgensen 1994: 57; Hårdh 1999: 159–161; Hårdh 2011: 59–61). Two pieces of Viking Age jewellery found melted together at the Hjulby settlement might represent a vivid illustration of the handling of scrap jewellery – perhaps the result of a disrupted melting down of jewellery intended for the production of new pieces (Henriksen 2002: 177, fig. 24). Signs of deliberate destruction of brooches noted at some sites are also a strong indication that scrap jewellery was recycled (Hårdh 2010: 273; Hedegaard 1989: 80). A few of the brooches from the Limfjord region do seem to have been deliberately damaged. Three are bent but otherwise very well-preserved, suggesting a very short stay in the plough soil, and a further nine appear to have suspiciously straight fractures, or are cut in places where brooches are solid and breakage is uncommon. However, in most cases it is impossible to establish with certainty whether the breakage happened prior to deposition or later as a result of advanced attrition.

In some cases, the distribution of the fragmented brooches also appears to support the fact that at least some parts of the fragmented material were actually scrap pieces circulating in workshop areas. At Uppåkra, Hårdh has noted that the most fragmented beak brooches are mainly restricted to two areas, which may be workshop areas (Hårdh 1999: 161). The concentration of the most fragmented brooches in areas characterised by traces of waste from workshops has also been recognised at Stavnsager, where the fragmented cruciform brooches from the Early Germanic Iron Age were predominantly recovered in the workshop area (Høilund Nielsen & Loveluck 2006: 74).³² Similar skewed patterns of fragmented brooches are not traceable in the Limfjord region. At the Østergaard settlement on the Nørholm hill, the most productive of the detector sites in the region, the fragmented beak brooches show a slight tendency to cluster in the north-eastern part of the settlement, which is characterised by scattered pit-houses. However, they are very scattered, and the number is modest. Nevertheless, two are fragments of unfinished brooches (Figure 6a–b) and perhaps some of the other fragments in

31 However, the gradual reduction of zinc and lead content during the melting process has necessitated some sort of fresh supply of alloy with a high content of zinc (Hedegaard 1992: 84)

32 At Hjulby on Funen, the brooches and other metal-detector finds have also predominantly been recovered in an area with thick cultural layers containing traces of different crafts. Henriksen believes many of these to be scrap metals for the workshops (Henriksen 2002).

the area were scrap metals circulating in the workshop area. On the other hand, contemporary brooches scattered outside the settlement area are even more fragmented.³³

Random loss or deliberate deposition?

If the many brooches do not come from ploughed-out scrap deposits or workshop areas, why did they end up in the soil? Could most of the brooches simply have been lost during use? At present, the most convincing answer to this, in the author's opinion, can be found in a study of Early Medieval brooches from England, where metal detectorists have also recovered large numbers of brooches (McLean & Richardson 2010). Through a comparative study of Early Medieval annular and cruciform brooches recovered in England, Mclean and Richardson have demonstrated clear discrepancies between the quantities of the different types of brooch found in graves and the types of brooch recovered by metal detectorists. The annular brooches are common finds in graves but are hardly ever recovered through metal detection, whereas cruciform brooches, the largest single class of Early Medieval brooch recovered by metal detectorists in England, are markedly underrepresented in graves. Interestingly, the annular brooch so rarely recovered by the metal detectorists has tended to be more securely fastened to the dress to which it was pinned owing to the basic principle of attachment, clearly suggesting that the underrepresentation of annular brooches in the record of metal-detected finds is reflective of this circumstance, and likewise that the overrepresentation of the cruciform brooches is the result of random loss during use (McLean & Richardson 2010: 165–167).

Other convincing arguments put forward in favour of this interpretation are the fact that many brooches seem intact with bits left of the pin construction (Vang Petersen 1991: 53), the general low level of damage (Haldenby & Richards 2010; Høilund Nielsen 2014: 28), and the fact that many brooches appear to be randomly distributed across settlements and in their immediate surroundings (Høilund Nielsen & Loveluck 2006: 73–74; Kershaw 2013: 184). The first issue is impossible to study from the varying records of the local museums in the Limfjord region, which often offer no description or photo of the back of the brooches, while the second has been addressed above. The third factor, spatial studies, may offer an opportunity to reveal meaningful patterns. However, a genuine comparison of the distribution of plough-layer metal-detector finds within the settlement remains requires a thoroughly metal-detected site, a good number of finds with properly recorded, preferably GPS-recorded, find locations, and knowledge of the extent of the settlement

³³ Nine of a total of 19 beak brooches found in the area with settlement structures and in the immediate surroundings (within a 100 zone around the settlement) were fragmented. Scattered outside this zone, detectorists have recovered additional 25 beak brooches, of which 16 are fragmented.

gained through supportive investigations. None of the sites in the Limfjord region fully meets these requirements. Even though the Østergård settlement on the Nørholm hill has only been investigated through a series of trial excavations, it is currently the site that offers the best data in this regard. There the brooches recovered were scattered across areas extending far beyond the edge of the settlement. However, the density of brooches is clearly much higher within the settlement than in the areas with most finds outside it.³⁴ The general concentration of all finds and the higher frequency of brooches within the settlement are also visible at Bejsebakken on the neighbouring hill, where investigations have been extensive, and at Vester Vandet in Thy. Unfortunately, at Bejsebakken most recordings of the find location are either lacking or very imprecise, which prevents exact calculation, and at Vester Vandet the exact extent of settlement remains to be explored. At the centre of the Vester Vandet settlement the density of the find population is c. one brooch per 550 square metres, compared to c. one per 1,100 square metres at the Østergård settlement. However, a straightforward comparison of the two sites is misleading, not just because there are chronological discrepancies, but also because settlement remains at Østergård are heavily ploughed out, in contrast to Vester Vandet, which is characterised by thick, rich culture layers that may still potentially contain a large proportion of finds.

Most settlements in the region seem to have stopped moving about during the seventh to ninth century and are thus covered by existing settlement, which impedes spatial studies of artefact scatters at the actual settlements. Apart from settlement from the fifth to seventh century, and perhaps little bits of later settlements found by the edge of existing villages, medieval settlement traces are missing in most areas. Nevertheless, the metal-detector finds everywhere point to a profound continuity if we look, at a slightly broader level, at what must have been the local resource areas. At most sites, brooches and other non-ferrous metal finds appear randomly mixed and widely scattered across vast areas next to the existing villages that are presumed to have roots in the seventh to eleventh century. At several sites, excavations have proven unable to locate evidence of any archaeological structures in these adjacent areas characterised by multiple metal-detector finds,³⁵ and given the extreme distribution, often covering more than 50 hectares,³⁶ it seems probable that most metal artefacts were dropped in the settlements and

³⁴ If comparing the GPS-recorded finds to the extent of settlement, 18 brooches contemporary to settlement have been found in the plough layer covering the area, 41 have been recovered within a 150m buffer zone immediately around the settlement, and five come from the buffer zone between 150 and 300m from the settlement. Additionally, 28 brooches have been found within the total area of this survey (find spots not recorded with GPS). If these are split in zones proportionally to the GPS-recorded finds, the density of brooches is c. 1 per 1,100 square metres in the settlement, c. 1 per 3,400 square metres within the 150m buffer zone, and c. 1 per 52,800 square metres within the 300m buffer zone.

³⁵ This has been demonstrated through large-scale trial excavations at Nørholm and Bejsebakken, and through minor trial excavations at Øster Vandet and Sønder Tranders.

³⁶ At Aggersborg and Nørholm, the finds are distributed across areas of more than 100 hectares, even if individual outliers are left out.

subsequently scattered on the cultivated fields in the surroundings, likely during the manuring of the fields (Trier Christiansen 2017: 63-66). Similar patterns have also been recognised during studies of other categories of finds in rural environments in south-eastern Denmark (Moesgaard & Tornbjerg 2011).

The fact that so many brooches were dropped at the settlements and never retrieved may seem remarkable. Nevertheless, given the right circumstances, even large eye-catching objects may be lost in high-activity zones. Some years ago, a local detectorist handed in a large, very shiny, gilded Urnes-style brooch at Moesgaard Museum, Aarhus – clearly a modern reproduction. It had been found during a survey of one of the fields close to the museum. The area is the scene of the annual Viking market, and the brooch must have been dropped there by one of the actors circulating at the market. It is noteworthy that the market held there takes place in the summer time and almost exclusively during the hours of full daylight, and moreover in areas predominantly covered by well-grazed grass, though of course this can become muddy on rainy days. For most of the time, conditions in the Iron Age and medieval settlements must have been much different, especially at night and at wintertime. Recovering a lost brooch in darkness in a muddy or even snow-covered activity zone in a settlement must have required a good deal of luck. The same was no doubt true if a brooch was dropped in the stable of a longhouse. That brooches were actually lost in the busy activity zones in and right around the longhouses in the Limfjord region has been demonstrated by two brooches found during the excavation of a well-preserved seventh-century longhouse in Tæbring: one was found inside, and one in a waste deposit right outside the building (Mikkelsen et al 2008: 85, fig. 3). In that perspective, the loss of brooches in great numbers appears plausible. Of course, the frequency of dropped brooches, as well as that of rediscovery, must have varied considerably. The size and colour of the brooches obviously influenced their visibility and thereby the chance of their recovery, but so also did the way they were worn. In particular, brooches essential to the function of dress must usually have been recovered immediately as the wearer would instantly be aware of the loss; not least must the frequency with which and the circumstances under which jewellery was worn have affected patterns of loss.

Considering the number of brooches found widely scattered at most sites in the Limfjord region, many brooches ended up in the manure. That brooches were occasionally lost in the stable may seem strange. However, animals and their keepers were not the only ones frequenting the stable, which also functioned as storage room, bedroom and work zone (e.g. Zimmermann 2015). The dim lighting and the bedding must have tended to hamper the recovery of lost artefacts, and the continuous adding of new bedding material probably gradually buried lost artefacts until they were eventually dug up and scattered in the fields. Furthermore, we must consider the possibility that various manuring strategies were practised. Some of these strategies probably involved different stages of storage and preparation of the raw materials at the settlement (Jones 2005), and each time there was the risk/chance of lost items, along

with settlement waste, ending up in the manure before it was spread onto the surrounding fields. Turf manuring, which has been widely practised in more recent times across large parts of western and northern Jutland, was probably the strategy that was adopted in the Limfjord region (Madsen & Vegger 1992; Stoklund 1990; Haack Olsen 2005).

Even though it seems that many brooches were just lost, it cannot be rejected that some of the widely scattered brooches were in fact deliberately deposited. A series of different scenarios may be envisioned for the deliberate deposition of brooches. A brooch may have been buried in a hoard, a treasure, or a grave, or it may simply have been tossed away after use. Given the value of the metal, this last is not likely to have been common behaviour, and hoards or treasures containing brooches are extremely rare or lacking in the region during most of the period studied here.³⁷ However, some of the metal-detected brooches predating the introduction of Christianity may come from eroded graves. A small number of Late Iron Age graves containing brooches have been excavated in the region. Compared to the number and variety of brooches recovered through metal detection, the grave finds are clearly not representative of the brooches in circulation, and the number of graves is too modest to make more detailed comparative analyses.³⁸ The one deviation that catches the eye when comparing the composition of the types of brooch found in graves and the composition of the record of the metal-detected brooches is the relative frequency of the large Viking Age tortoise brooches compared to the other brooches of the period. The tortoise brooch is represented only by a modest 22 fragmented pieces, but is by far the most frequent type of brooch found in the graves of the region. At Lindholm Høje, the only site that has yielded several graves containing Viking Age brooches, six of eight identifiable brooches were tortoise brooches, and another three fragmented pieces may also belong to this category (Ramskou 1976). Even considering the different methods of recovery, this discrepancy is so marked that it must to some degree reflect a true difference between what was lost at the settlements and what ended up in the graves. Perhaps this could just be a pattern generated by the fact that the large tortoise brooches were more often rediscovered when lost than other types of brooch; perhaps more likely, considering the relatively high number of other large, contemporary brooches like the trefoil brooches recovered by the metal detectorists, is that the

37 The only exceptions are two Viking Age deposits with sets of tortoise brooches (no. of location: 130409–53 and ÅHM 4125a-b (Johansen 1992: 93), as well as a possible hoard which contained a full set of jewellery dated Early Germanic Iron Age (No. of location: 130911-69). For a case of ritual deposition of brooches on Öland, Sweden, see (Fallgren & Ljungkvist 2016).

38 Quite a few graves from the Early Germanic Iron Age contain cruciform brooches (e.g. Nielsen 2000; Råmskou 1976; Trier Christiansen 2006). Graves dated to Late Germanic Iron Age are very rare, and well-equipped ones almost absent. But at the Lindholm Høje burial ground, 27 graves contained brooches from this period. Viking Age graves with brooches are likewise rare. Apart from 9–10 graves from Lindholm Høje, only a few have been found scattered in the region (Råmskou 1976: Grave 1124, 1176, 1230, 1244, 1346, 1626, 1655, 1720; Johansen 1992: 93–94; Pedersen 2014: cat.no. 175, 187, 192, 293).

discrepancy reflects differences between everyday dress and more formal dress worn only on special occasions.

At present, the modest number of graves with brooches rules out the generation of a predictive model for recognition of potential grave goods hiding in the record. The assistance we might have hoped to gain through spatial analysis is reduced because of the pervasive redepositing of the small metal artefacts.

Conclusion: the use and deposition of brooches in the Limfjord region AD 400–1150

Summing up, the abundance of brooches recovered in the Limfjord region seems to suggest that the production of brooches was a common phenomenon across the region throughout the period of AD 400–1200 – an assumption that at present is supported mainly by a few scattered finds of models and unfinished brooches and scattered evidence of workshop areas. Furthermore, variation in the brooch inventory and interregional spatial patterns seem to signal changing modes of production over the centuries.

Because the interpretational support offered by the plough layer is so weak, inferences regarding the original deposition of finds recovered from this layer are always going to be somewhat speculative, but indications are that most of the brooches recovered in the Limfjord region ended up in the soil as a result of accidental loss at settlements. Furthermore, analyses of the fragmentation and preservation of the surface of the brooches suggests that cultivation constitutes the prevailing cause of brooch fragmentation. This is despite the fact that, not surprisingly, local environmental conditions also affect the preservation of the brooches and thus also the composition of assemblages from varying sites. In the Limfjord region the metal objects at sites to the west, where the soil is sandy, are in general poorly preserved compared to especially the finds from the alkaline soil of the chalky hills in the centre of the region.

The outline of a depositional biography of the brooches which has been sought in the present paper is further hampered by the widespread redepositing of objects that are presumed originally lost at the settlements. At many sites, the metal-detector finds are found randomly mixed and spread across vast areas in the surroundings of the settlements. The secondary distribution probably took place during manuring of nearby fields, rendering it likely that spatial studies may be better suited to the study of agricultural strategies than to the investigation of primary depositional activities.

A central aspect carefully avoided in this paper is the question of quantitative differences between sites. Why are there so many brooches at some sites, and few or none at others? Following the general interpretation suggested here, the number of brooches may serve as a rough guideline for the number of well-dressed women having frequented the sites. This does not

necessarily imply that women outnumbered men, as the inventory of Danish graves indicates that male equipment rarely included items of non-ferrous metals throughout the Late Iron Age. Interestingly, such a direct relationship between the population size and the amount of waste has consistently been demonstrated in English surveys of medieval field systems; only here numerous pottery sherds have served as an indicator (Jones 2005: 171).

Taking the interpretation one step further, different socio-economic factors must have influenced the intensity and character of activity, and thus the number of brooches and other metal objects circulating at the settlements. At present, the modest knowledge of many sites provides us with little opportunity for comparative studies. Even basic information about structure and economy is lacking from many settlements. In the Limfjord region, the one obvious element shared by all the sites that have yielded most detector finds from the period AD 400-1150 (including brooches) is a distinct coastal orientation. The 15 detector sites that have produced the most finds are all located at least 5 km from the coast, suggesting the paramount importance of marine resources (Trier Christiansen 2017: 115-116). Variation within this group of settlements is apparently limited. Most settlements seem to have been agrarian, but a few, situated directly on the coast, may have relied primarily upon fishing. Furthermore, settlement remains from both types of site typically include large numbers of sunken-featured buildings, suggesting that some kind of specialised production was often carried out there - predominantly textile production based upon finds recovered from the floors of many of the buildings. As suggested elsewhere, large-scale production of textiles for use in sails seems to be a likely explanation for the development of this dense coastal settlement of specialised villages, involving hundreds of sunken-featured buildings. On this basis, it is tempting to propose a direct link between the women operating the looms and the high frequency of brooch loss at the coastal settlements (Trier Christiansen 2017: 165)

Surely many of the generalising interpretations presented above needs refining, and future research will no doubt uncover patterns that are capable of refining it. However, a prerequisite for this is a fundamental improvement in the interpretational framework for the understanding of metal-detector finds. Even though much has been done in recent years at many sites, systematic metal detecting combined with extensive supportive investigations at more sites would supply a firmer base for the interpretation of the fantastic find material that has been recovered by the private detectorists on their relatively random searches. In addition, new insights could undoubtedly be achieved through more detailed examinations of the brooches than have been possible in this pilot study. Analyses of alloys, breakages, construction and ornamentation would surely answer a number of questions regarding both patterns of production and consumption, as well as preservation

Acknowledgements

This paper has benefited significantly from the kind support of many. I would like to thank Søren M. Sindbæk, Andres Dobat, and Torben Sarauw for their comments on earlier drafts. Furthermore, the determination of the many brooches has brought me into contact with many helpful fellow scholars across north-western Europe. For advice and comments on challenging brooches, I thus thank Karen Høilund Nielsen, Claus Feveile, Mogens Bo Henriksen, Anne Pedersen, Pieterjan Deckers, Maria P. Bastrup, Martin Rundkvist, Else Roesdahl, Peter Vang Petersen, Toby Martin, Nelleke IJssennagger, James Graham-Campbell, and Volker Hilberg. Thanks also go to Aarhus University, the Historical Museum of Northern Jutland, Museum Thy, and the Danish Agency for Culture for the financial support I received while working on this paper as a part of my PhD scholarship, and to the helpful staff at the local museums in the Limfjord region who eased my access to the data needed for this study and patiently answered my numerous questions. Last but not least, I extend thanks to the many private detectorists who have supplied me with additional information on selected brooches that were otherwise inaccessible to me, and, of course, to all the metal detectorists for their decisive efforts in the field.

Catalogue

Introduction

This catalogue contains lists of all brooches and brooch models (dated to the period between AD 400 and 1150) recovered through metal detection in the Limfjord region. It consists of two main parts: (1) Brooches, and (2) Models; and the content and structure of these are:

List 1: Brooches

Lists of all brooches (dated to the period between AD 400 and 1150) recovered through metal detection in the Limfjord region. The brooches in the list are divided into four main groups according to dating: 1.1. The Early Germanic Iron Age, 1.2. The Late Germanic Iron Age, 1.3. The Viking Age, 1.4. The Viking Age-The Early Middle Ages and 1.5. The Early Middle Ages. Furthermore, the brooches are sorted secondarily alphabetically into main types. Within every group of main types, the brooches are listed according to the name of the find location; in the case of multiple brooches of the same type from the same find location, they are sorted according to the find numbers of the local museum, starting with the smallest number.

The list consists of six columns containing: (1) catalogue number; (2) the journal/case number of the local museum; (3) the find number issued by the local museum; (4) the name of the find location (In quite a few cases, separate sites have over the years merged because of increasing numbers of finds in the empty areas that originally separated the sites. This has led to some confusion as to the naming of the sites, as some names referred to, for example, a single field or road, even though the site ended up covering an entire hill. In the case of multiple names, the name referring to the full find area has been chosen. However, the older names/subdividing names are noted in parenthesis; and (5) the material of which the brooch is made (None of the brooches have been analysed. Thus, all information on alloys relies on visual inspection); (6) level of fragmentation; and (7) type/description. References to the typologies used are listed at the end of the sub-lists. Regarding the level of fragmentation, the term “large fragment” refers to fragments estimated to represent more than half of the brooch, while “small fragment” refers to fragments representing less than half of the brooch.

List 2. Models

List of models for the production of brooches (dated to the period between AD 400 and 1150) recovered through metal detection in the Limfjord region. The models are listed alphabetically according to the type of the object and secondarily according to the name of find location (alphabetically); in the case of multiple objects of the same find location, they are sorted according to the museum numbers and subsequently to the find numbers, starting with the smallest number.

Dating codes: EGIA = Early Germanic Iron Age (c. 400-550 AD); LGIA = Late Germanic Iron Age (c. 550-800 AD); VKA = Viking Age (c. 800-1050

AD); EMA = Early Middle Ages (c. 1050-1150); and LIA = Late Iron Age (c. 400-1050).

Data on the metal-detector finds has primarily been collected at the six local museums of the region – the Historical Museum of Northern Jutland, Museum Thy, MUSE[®]UM (Skive), the Museum of Holstebro, the Museum of Viborg, and the Museum of Vesthimmerland. Data collection was completed by July 2014. The one exception is the Vester Vandet site in the western end of the region, from where the continuous flow of incoming data was not discontinued until the end of 2015.

1.1. Brooches - The Early Germanic Iron Age

Cat. no.	Museum no.	ID	Site	Material	Degree of fragmentation	Type
1	ÅHM 0961	C30748	Bejsebakken (Skelagervej/Sofiendal)	Copper alloy	Small fragment	Bow brooch - semicircular head plate
2	ÅHM 0961	Unknown	Bejsebakken (Skelagervej/Sofiendal)	Copper alloy	Small fragment	Bow brooch - type?
3	ÅHM 0961	Unknown	Bejsebakken (Skelagervej/Sofiendal)	Copper alloy	Unknown	Bow brooch - type?
4	ÅHM 5510	D001-1	Klarupgård	Copper alloy	Small fragment	Bow brooch - type?
5	ÅHM 6309	K025-20	Nørholm	Copper alloy	Small fragment	Bow brooch - type?

8	ÅHM 5595	X12	Sdr.Tranders Sdr.Tranders Kirke)	Copper alloy	Small fragment	Bow brooch - type?
9	ÅHM 6303	K005-3	Sdr.Tranders (Sdr.Tranders Kirke)	Copper alloy	Small fragment	Bow brooch - type?
10	VSM 9814	X1	Stenshøje Vest	Copper alloy	Small fragment	Bow brooch - type?
11	THY 6060	X75	Vang	Copper alloy	Small fragment	Bow brooch - type?
12	HOL 20.599	X62	Vester Rysensten	Copper alloy	Unknown	Bow brooch - type?
13	THY 3719	X196	Vestervig	Copper alloy	Small fragment	Bow brooch - type?
14	VSM 9687	X112	Øster Kølsen	Copper alloy	Small fragment	Bow brooch - type?
15	THY 5045	X364	Øster Vandet	Copper alloy	Small fragment	Bow brooch - type?
16	THY 6141	X72	Vester Vandet (Tandrup)	Copper alloy	Small fragment	Bow brooch with circle ornaments on foot/head plate
17	ÅHM 5177	K157-7	Nørholm	Copper alloy	Large fragment	Bow brooch with foot plate of three concentric circles (Fig. 2h)
18	ÅHM 5593	D001-3	Nr.Tranders/ Ø. Uttrup (Ø. Uttrup)	Copper alloy	Large fragment	Bow brooch with foot plate of three circles
19	ÅHM 4952	X2	Nørholm	Bejsebakken (Skelagervej/Sofiendal)	Copper alloy	Bow brooch with rectangular head plate
20	ÅHM 0961	Unknown	Øster Vandet	Tinned copper alloy	Large fragment	Bow brooch with ribbed foot
21	THY 5045	X526	Øster Vandet	Copper alloy	Large fragment	Bow brooch with semicircular head plate
22	ÅHM 5181	D004	Nørholm	Copper alloy	Large fragment	Bow brooch with semicircular foot plate
23	ÅHM 5178	D093-2	Nørholm	Copper alloy	Small fragment	Bow brooch with small triangular foot
24	THY 5045	x73	Øster Vandet	Copper alloy	Large fragment	Bow brooch with spade-shaped foot
25	ÅHM 5918	K042-1	Als	Copper alloy	Small fragment	Bow brooch with triangular foot

26	VMA 2674	x654	Aggersborg Bejsebakken (Skelagervej/ Sofiendal)	Copper alloy	Unknown	Brooch - type?
27	ÅHM 0961	C30719?	Nr. Tranders / Ø. Uttrup (Humlebakken)	Copper alloy	Small fragment	Brooch - type?
28	ÅHM 1661	Unknown	Nr. Tranders / Ø. Uttrup (Humlebakken)	Copper alloy	Unknown	Brooch - type?
29	THY 6141	X79	Vester Vandet (Tandrup)	Copper alloy	Small fragment	Brooch - type?
30	ÅHM 4959	Unknown	Nørholm	Copper alloy	Large fragment	Brooch with cruciform head plate
31	ÅHM 5918	K017-2	Als	Copper alloy	Large fragment	Brooch with cruciform head plate (small-long brooch)
32	ÅHM 5180	D010-1	Nørholm (Nørholm (Mellemholt))	Copper alloy	Large fragment	Brooch with rectangular head plate
33	ÅHM 4823	X18	Vester Hassing	Copper alloy	Small fragment	Brooch with rectangular head plate
34	ÅHM 2403	X10	Sebbersund	Copper alloy	Whole	Brooch with rectangular head plate and spade-shaped foot (small long-brooch - Fig. 2e)
35	ÅHM 5178	K192-6	Nørholm	Copper alloy	Whole	Brooch with rectangular head plate and spade-shaped foot (small long-brooch)
36	THY 3719	X120	Vestervig	Copper alloy	Small fragment	Brooch with rhombic head plate
37	THY 3924	X168	Østerild	Copper alloy	Small fragment	Brooch with semicircular head plate and three knobs
38	VMA 2376	C 36338	Soldalgård I	Copper alloy	Unknown	Brooch with spade-shaped foot
39	VMA 2376	Unknown	Soldalgård I	Copper alloy	Unknown	Brooch with spade-shaped foot
40	ÅHM 5182	K107-1	Sønderholm	Copper alloy	Large fragment	Brooch with spade-shaped foot
41	ÅHM 5177	K137-3	Nørholm	Copper alloy	Small fragment	Brooch with triangular foot
42	ÅHM 0960	K56-1	Bejsebakken (Stolpedalsvej)	Copper alloy	Unknown	brooch with wide foot plate
43	ÅHM 0961	C30544	Bejsebakken (Skelagervej/ Sofiendal)	Copper alloy	Whole	Crossbow brooch
44	ÅHM 4856	X5	Nørholm (Nørholm (Mellemholt))	Copper alloy	Whole	Crossbow brooch with kringle-shaped foot (Ozingell brooch)
45	ÅHM 5178	K142-1	Nørholm	Copper alloy	Whole	Crossbow brooch with spiral foot, ending in a bird's head with curved beak (Fig. 45)
46	ÅHM 0961	Unknown	Bejsebakken (Skelagervej/ Sofiendal)	Copper alloy	Small fragment	Cruciform brooch?
47	VMA 2674	x1086	Aggersborg	Copper alloy	Large fragment	Cruciform brooch
48	VMA 2674	x691	Aggersborg	Copper alloy	Large fragment	Cruciform brooch
49	ÅHM 5918	K005-1	Als	Copper alloy	Large fragment	Cruciform brooch
50	ÅHM 5918	K113-8	Als	Copper alloy	Large fragment	Cruciform brooch
51	ÅHM 1482	X2	Bejsebakken	Copper alloy	Fragmented (extent of fragmentation unknown)	Cruciform brooch

52	ÅHM 4948	Unknown	Bejsebakken (Gl.Hasseris) Bejsebakken (Skelagervej/ Sofiendal)	Copper alloy	Whole	Cruciform brooch
53	ÅHM 0961	C30731	Bejsebakken (Skelagervej/ Sofiendal)	Copper alloy	Large fragment	Cruciform brooch
54	ÅHM 0961	C30736	Bejsebakken (Skelagervej/ Sofiendal)	Copper alloy	Small fragment	Cruciform brooch
55	ÅHM 0961	C30757	Bejsebakken (Skelagervej/ Sofiendal)	Copper alloy	Small fragment	Cruciform brooch
56	ÅHM 0961	C30766	Bejsebakken (Skelagervej/ Sofiendal)	Copper alloy	Small fragment	Cruciform brooch
57	ÅHM 0961	C30767	Bejsebakken (Skelagervej/ Sofiendal)	Copper alloy	Small fragment	Cruciform brooch
58	ÅHM 0961	C30772	Bejsebakken (Skelagervej/ Sofiendal)	Copper alloy	Small fragment	Cruciform brooch
59	ÅHM 0961	C30978	Bejsebakken (Skelagervej/ Sofiendal)	Copper alloy	Small fragment	Cruciform brooch
60	ÅHM 0961	Unknown	Bejsebakken (Skelagervej/ Sofiendal)	Copper alloy	Large fragment	Cruciform brooch
61	ÅHM 0961	Unknown	Bejsebakken (Skelagervej/ Sofiendal)	Copper alloy	Large fragment	Cruciform brooch
62	ÅHM 0961	Unknown	Bejsebakken (Skelagervej/ Sofiendal)	Copper alloy	Small fragment	Cruciform brooch
63	ÅHM 0961	Unknown	Bejsebakken (Skelagervej/ Sofiendal)	Copper alloy	Small fragment	Cruciform brooch
64	ÅHM 0961	Unknown	Bejsebakken (Skelagervej/ Sofiendal)	Copper alloy	Small fragment	Cruciform brooch
65	ÅHM 0961	Unknown	Bejsebakken (Skelagervej/ Sofiendal)	Copper alloy	Small fragment	Cruciform brooch
